# Detailed steps to execute the program with screenshots of the execution results:

Create the Project Directory:

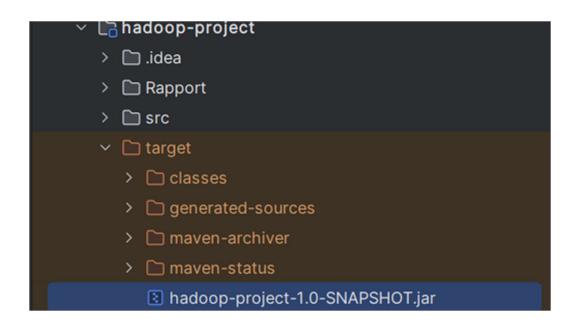

On your machine, create a directory structure as follows: Docker/Labs/Project

Place the following files in the Project directory:

- docker-compose.yml
- hadoop.env

In hadoop-project code, generate: hadoop-project-1.0-SNAPSHOT.jar using:

mvn clean package

### Add Required Files:

Place the following additional files in the Project directory:

- hadoop-project-1.0-SNAPSHOT.jar
- ml-25m folder (containing movies.csv and ratings.csv)

Copy Files to HDFS:

Follow these steps to copy files from your local file system to the Hadoop Distributed File System (HDFS), this is an example with movies file:

• Create the target directory in HDFS for the dataset (ml-25m):

```
hdfs dfs -mkdir -p /ml-25m
```

• Copy the movies.csv file to the ml-25m directory in HDFS:

```
hdfs dfs -put /Docker/Labs/Project/ml-25m/movies.csv /ml-25m/
```

```
root@e0f7d2118a11:/hadoop/labs# hdfs dfs -mkdir -p /ml-25m
root@e0f7d2118a11:/hadoop/labs# ls
current docker-compose.yml hadoop-project-1.0-SNAPSHOT.jar hadoop.env in_use.lock ml-25m test
root@e0f7d2118a11:/hadoop/labs# hdfs dfs -put /hadoop/labs/ml-25m/ratings.csv /ml-25m/
put: `/ml-25m/ratings.csv': File exists
root@e0f7d2118a11:/hadoop/labs# hdfs dfs -put /hadoop/labs/ml-25m/movies.csv /ml-25m/
put: `/ml-25m/movies.csv': File exists
root@e0f7d2118a11:/hadoop/labs# hdfs dfs -put /hadoop/labs/ml-25m/movies.csv /ml-25m/
```

Navigate to the Docker/Labs/Project directory in your terminal and run docker compose up

Open a new terminal and execute the following command to enter the namenode container:

```
docker exec -it namenode bash
```

Once inside the container, navigate to the labs directory using:

```
cd hadoop/labs
```

```
PS C:\Users\maroi> docker exec -it namenode bash
root@e0f7d2118a11:/# ls
                                      home lib64
KEYS boot entrypoint.sh hadoop
                                                   mnt
                                                        proc
                                                              run
                                                                      sbin
                                                                           sys
                                                                                usr
bin
     dev etc
                          hadoop-data lib
                                            media opt
                                                        root run.sh
                                                                     srv
                                                                                var
                                                                           tmp
root@e0f7d2118a11:/# cd hadoop/labs
root@e0f7d2118a11:/hadoop/labs# ls
                   hadoop-project-1.0-SNAPSHOT.jar in_use.lock test
current
docker-compose.yml hadoop.env
                                                   ml-25m
root@e0f7d2118a11:/hadoop/labs#
```

Run the HighestRatedMovie Hadoop Job:

### HighestRatedMovie.java

This class finds the highest-rated movie for each user:

- RatingMapper: Processes input data in CSV format, skips header, and emits (userld, movield:rating) pairs
- RatingReducer: For each user, finds the movie with the highest rating and outputs (userId, movieId)

Execute the following command to run:

```
hadoop dfs -rm -r /output1 ; hadoop jar hadoop-project-1.0-SNAPSHOT.jar com.example.hadoop.HighestRatedMovie /ml-25m/ratings.csv /output1
```

### Execution results:

```
Monthin: the of this script to execute off is depreciated.

Monthin: the off this script to execute off is depreciated.

Monthin: attempting to execute spin-separated.

Month
```

You can see the content of output1 using command:

```
hadoop fs -cat /output1/part-r-00000
```

Let's just expose 20 lines:

```
hadoop fs -cat /output1/part-r-00000 | head -n 20
```

## MovieJoin.java:

This class performs a join operation between user-movie data and movie metadata:

- UserMovieMapper: Processes user-movie viewing data, emits (movield, "USER:userId")
- MovieMapper: Processes movie metadata, skips header, emits (movield, "MOVIE:movieName")
- JoinReducer: Joins the data by matching movies with users, outputs (userld, movieName) pairs

To run the MovieJoin job, execute the following command:

```
hadoop dfs -rm -r /output2; hadoop jar hadoop-project-1.0-SNAPSHOT.jar com.example.hadoop.MovieJoin /output1 /ml-25m/movies.csv /output2
```

```
MARRIEN: Use of this script to execute fig. 1 Address part to group of 2: Address Active to this script to execute fig. 1 Address Active to this script to execute fig. 2 Address Active to this script to execute fig. 2 Address Active to this script to execute fig. 2 Address Active to the Script to execute fig. 2 Address Active to the Script to execute fig. 2 Address Active to the Script to execute fig. 2 Address Active to the Script to the Script
```

You can see the content of output2 using command:

```
hadoop fs -cat /output2/part-r-00000
```

Let's just expose 20 lines:

```
hadoop fs -cat /output2/part-r-00000 | head -n 20
```

# MovieCountGrouping.java:

This class performs two sequential MapReduce jobs:

• The first job counts how many users watched each movie:

- MovieCountMapper: Takes input data and emits (movie\_name, 1) pairs
- MovieCountReducer: Sums up all the counts for each movie
- Second job groups movies by their view count:
  - o GroupingMapper: Takes the results from first job and inverts key-value pairs
  - o GroupingReducer: Groups all movies with the same view count together

To run the MovieJoin job, execute the following command:

```
hadoop dfs -rm -r /final_output ; hadoop jar hadoop-project-1.0-SNAPSHOT.jar

com.example.hadoop.MovieCountGrouping /output2 /final_output

rectee(P70211811:/Mosteps/labst hadoop dfs -rm -r /final_output; hadoop jar hadoop-project-1.0-SNAPSHOT.jar com.example.hadoop.MovieCountGrouping /output2 /final_output

MMDNING: Use of this script to execute offs is deprecated.

MMDNING: Actempting to execute explacement *hofs dfs* instead.

rm -/final_output: No such file or directory.

### **N.B**:

If you get any error related to a temporary file when launching a Hadoop command, just delete it. Here is an example of such situation:

```
inceteoffdilabil/Madoop/kabst hadoop dfs -rm -r/final_output; hadoop jar hadoop-project-1.0-SNAPSHOT.jar com.example.hadoop.MovieCountGrouping /output2 /final_output
MARRING: Attempting to execute replacement haffs dfs' intead.

Deleted /final_output

2024-12-08 11:33:27,493 IMFO client.RMProxy: Connecting to ResourceManager at resourcemanager/172.18.0.6:8032
2024-12-08 11:33:27,493 IMFO client.AMSProxy: Connecting to ResourceManager at the interval for the interval for a control of the control o
```

In this case, we try to execute the following command:

```
hadoop dfs -rm -r /final_output ; hadoop jar hadoop-project-1.0-SNAPSHOT.jar com.example.hadoop.MovieCountGrouping /output2 /final_output
```

The error shows the following:

```
Output directory hdfs://namenode:9000/final_output_temp already exists
```

We proceed with the deletion of the temporary file:

```
hadoop dfs -rm -r /final_output_temp
```

Re-execute your command and it will be launched correctly.
